Preface

About the notes

- This script aims to support my lecture at the HS Fresenius. It is incomplete and no substitute for taking actively part in class.
- The old version of the notes can be found here PDF.
- I appreciate you reading it, and I appreciate any comments.
- This is work in progress so please check for updates regularly.
- The lecture notes are available online or you can download it as a [pdf file here](#)

About the author

Figure 1: Prof. Dr. Stephan Huber¹

Prof. Dr. Stephan Huber is Professor of International Economics and Data Science at *HS Fresenius* and holds a Diploma in Economics from the *University of Regensburg* and a Doctoral Degree (summa cum laude) from the University of Trier. He completed postgraduate studies at the Interdisciplinary *Graduate Center of Excellence at the Institute for Labor Law and Industrial Relations in the European Union (IAAEU)* in Trier. He was a research assistant to Prof. Dr. Dr. h.c. Joachim Möller at the *University of Regensburg*, post-doc at the *Leibniz Institute for East*

¹Picture is taken from <https://sites.google.com/view/stephanhuber>

and *Southeast European Studies (IOS)* in Regensburg and freelancer at *Charles University* in Prague.

He has worked as a lecturer at various institutions including the *TU Munich*, the *University of Regensburg*, *Saarland University*, and the *Universities of Applied Sciences in Frankfurt and Augsburg*. He has also taught abroad for the *University of Cordoba* in Spain and the *University of Perugia*. Professor Huber has published his work in international journals such as the *Canadian Journal of Economics* and the *Stata Journal*. More on his work can be found on his private homepage www.t1p.de/stephanhuber.

About this course

Workload of M-IBS 8 Quantitative & Qualitative Methods for Business
125 h = 56 h (in-class) + 21 h (guided private study hours) - 48 h (private self-study).

Workload of M-IBS 8.1 Quantitative Methods 62.5 h = 28 h (in-class) + 10.5 h (guided private study hours) - 24 h (private self-study).

Assessment Students complete this module with a written exam of 120 minutes where 50% of the points stem from *M-IBS 8.1 Quantitative Methods* and 50% from *M-IBS 8.2 Qualitative Methods*. A passing grade in this module is achieved when the overall grade is greater than or equal to 4.0.

Learning outcomes: After successful completion of the module, students are able to:

- assess and discuss coherent research paradigms, based on quantitative, qualitative, and mixed-methods research approaches,

- explain a broad set of quantitative and qualitative methods to collect, gather, illustrate, analyze, and interpret data,
- distinguish and discuss empirical strategies to identify causal mechanisms, causes, and effects.

How to prepare for the exam: I am convinced that reading the lecture notes, preparing for class, taking actively part in class, and trying to solve the exercises without going straight to the solutions is the best method for students to

- maximize leisure time and minimize the time needed to prepare for the exam, respectively,
- getting long-term benefits out of the course,
- improve grades, and
- have more fun during lecture hours.

Literature: Cunningham (2021), Huntington-Klein (2022). Illowsky and Dean (2018). Békés and Kézdi (2021)

Content:

Research Design

- How to Measure Socio-Economical Reality
- How to Identify Causes of Effects
- How to Identify Effects of Causes
- The Selection Problem and Ways to Solve It (Matching, Natural Experiments, Laboratory Experiments)

Statistical Toolbox

- Types of Data (Cross-section, Panel, Time-series, Georeferenced),
- Types of Variables (Continuous, Count, Ordinal, Categorical, Qualitative)
- Data Sampling Methods
- Descriptive Methods (Data Visualization, Statistical Moments, Correlation)
- Methods of Statistical Inference (Distribution, Statistical Tests)
- Mathematical and Statistical Software Packages (R, SPSS, Excel, WolframAlpha, etc.)

Methods

- Data Mining (Graphical Visualizations, Cluster Analysis, Factor Analysis)
- Regression Analysis (Matching, Instrument Variables, Difference in Difference, Fixed Effects, Regression Discontinuity)
- Other Methods (Time Series Analysis, Spatial Analysis, Simulations, Qualitative Comparative Analysis, etc.)

About how to learn (and prepare for the exam)

Figure 2: Richard P. Feynman's badge photo from Los Alamos National Laboratory³

Richard P. Feynman:

“I don’t know what’s the matter with people: they don’t learn by understanding; they learn by some other way – by rote, or something. Their knowledge is so fragile!”

Stephan Huber:

“I agree with Feynman: The key to learning is understanding. However, I believe that there is no understanding without practice, that is, solving problems and exercises by yourself with a pencil and a blank sheet of paper without knowing the solution in advance.”

- Study the lecture notes, i.e., try to understand the exercises and solve them yourself.
- Study the exercises, i.e., try to understand the logical rules and solve the problems yourself.

³Picture is taken from <https://repository.aip.org/islandora/object/nbla%3A299600>

- Test yourself with past exams that you will find on ILIAS. The structure of the exam is more or less the same every semester.
- If you have the opportunity to form a group of students to study and prepare for the exam, make use of it. It is great to help each other, and it is very motivating to see that everyone has problems sometimes.
- If you have difficulties with some exercises and the solutions shown do not solve your problem, ask a classmate or contact me. I will do my best to help.

Personal note

Dear students,

If the title of this course “Quantitative & Qualitative Methods for Business” seems uninteresting to you, I assure you that it is actually quite exciting because it focuses on how we can use information to understand how the world and business works and how to interpret facts. The course will enhance your data literacy, help you think critically, and improve your personal decision-making skills.

One way we can do this is by understanding the differences between quantitative and qualitative data and how they can be used to inform our choices.

Quantitative data is information that can be measured, such as numbers and statistics, while qualitative data is information that cannot be measured and is often expressed in words or other non-numerical forms.

Both forms of information are crucial for making good decisions. Without sufficient information, it can be difficult to evaluate the options and potential outcomes of a decision, leading to poor or uninformed choices. In general, the more information a decision-maker has and the faster and better the information can be used, the better they will be to make a sound decision.

The methods we discuss in this course will help you systematically gather information and make sense of it.

Enjoy the course!

Chapter 1

Doing research

Figure 1.1: Causal Inference: The Mixtape. A textbook by Scott [Cunningham \(2021\)](#).

“True scientists do not collect evidence in order to prove what they want to be true or what others want to believe. That is a form of deception and manipulation called propaganda, and propaganda is not science. Rather, scientific methodologies are devices for forming a particular kind of belief. Scientific methodologies allow us to accept unexpected, and sometimes undesirable, answers.” ([Cunningham, 2021](#), p. 10)

1.1 Everybody can do research

Research often involves exploring unknown territory and seeking out new information through methods such as attending conferences, conducting interviews and experiments, and reading related research. This process can lead to the discovery of valuable techniques or insights that address important issues in society or science.

Figure 1.2: Zora Neale Hurston, 1891-1960¹

“Research is formalized curiosity. It is poking and prying with a purpose.” (Hurston, 2010)

Before I go into how empirical research can and should be conducted, I would like to assert that each of us is a researcher in some sense and that you don't need a degree or a higher education to be a (good) researcher. Each of my four children (ages 2, 5, 6, and 8), for example, explores the world and learns something new every day. Even though none of my children is yet able to verify the novelty of their acquired knowledge and write it down in scientific form, I will claim that mine, like practically all children, are already little scientists. Why? Well, they explore unknown territory and search for information to discover new techniques that will make their lives pleasant. Of course, they don't attend conferences or read journals to do this. They have never heard terms such as ontology, epistemology, axiology, or quantitative and qualitative methods. They are using methods that they have mastered for their age. They interview me, my wife and all other people around and they conduct experiments. For example, all my children liked to throw plates, cutlery, cups and alike from the table when they were about one year old. At first the throwing was just an accident, but they quickly found out that each

¹Photography is taken from Library of Congress: Prints & Photographs Division, Carl van Vechten Collection, Reproduction Number LC-USZ62-54231, see: [https://www.loc.gov/pictures/item/2004663047/..](https://www.loc.gov/pictures/item/2004663047/)

throw was followed by a sound when the object touched the stone floor. My first son, in particular, took great delight in making these sounds. He threw everything within reach to the ground and giggled with joy at the clink he made when the object hit the ground. Perhaps he was also enjoying the attention he was getting from us parents through these actions. In any case, the behavior annoyed us. Wiping food scraps off the floor is not a nice thing to do. Unfortunately, at that time my son did not accept any argument to refrain from throwing. Neither a stern look nor a definite “no” helped to stop this behavior. Too great was the joy at the relationship he had figured out, which was, “I throw something off the table and it always clangs beautifully loud.” So I started to do some research to figure out what I could do to stop him. The short answer I found can be summed up pretty well as “nothing”. There is practically no good method to change the behavior without possibly negatively influencing his early childhood development. The reason is he did some research and we should not suppress that. Besides nature and material research he did social research: He found out that things fall to the ground (gravity), that things break and make different sounds (material research), and that other people notice him when he throws things (social research).

Figure 1.3: Children as little researcher²

Once, when we were eating at a friend’s house, my son (once again) threw everything off the table one after the other in unobserved moments. This time, however,

²Image by macrovector on Freepik, see: https://www.freepik.com/free-vector/kindergarten-set-isolated-icons-with-toys-characters-kids-practicing-with-teacher-playing-games-vector-illustration_26760074.htm

it made no noise. The carpet under the table muffled everything. My son was irritated and at some point became really angry. Why? Well, his surely believed reality and his law “I throw something from the table and then it always clangs beautifully loud.” was falsified. Soon he understood that his law only had to be adapted a little. It was then: “I throw something from the table and it clangs then beautifully loudly if a stone floor is under me.” He repeated his experiments for a few more weeks, to check its validity. In the meantime he does other experiments trying to contribute to his own knowledge.

In general, the purpose of research is to find new knowledge or discover new ways to use existing knowledge in a creative way so as to generate new concepts, methodologies, inventions and understandings that -now or later- may be of some value for the human mankind. In simple terms, we aim to find something out. We aim to find a new law, a new relationship, a new insight. Or, we aim to challenge and revise existing insights on how the world works. You don’t need a degree to do that. All you need is interest, open-mindedness, and a willingness to revise your ideas about how the world works. The latter is perhaps the most important skill you need to be a good researcher. Otherwise, one is a narrow-minded, and bigoted person who is too proud to follow up an insight with a change of mind.

I myself have a quick and happy tendency to change my views because it is a statement of a fresh understanding. Here are two more quotes from historically more significant people than me that are along the same lines and should convince you that changing your mind is not a sign of weakness, but of strength. Especially in science, the willingness to change one’s mind is essential.

Figure 1.4: John Maynard Keynes (1883-1946)³

“*When the facts change, I change my mind. What do you do, sir?*”⁴

³Photography is public domain and stems from https://de.wikipedia.org/wiki/John_Maynard_Keynes#/media/File:Keynes_1933.jpg

⁴This quote is often attributed to Keynes, but there is no clear evidence for it, see: <https://quoteinvestigator.com/2011/07/22/keynes-change-mind/>

⁵This photography from 1952 is public domain and stems from the Bundesarchiv, B 145 Bild-F078072-0004, Katherine Young, CC BY-SA 3.0 DE.

Figure 1.5: Konrad Adenauer (1876-1967)⁵

“What do I care about the rubbish I said yesterday? No one can stop me from getting smarter every day.” (“Was interessiert mich mein Geschwätz von gestern? . . . es kann mich doch niemand daran hindern, jeden Tag klüger zu werden.”)⁶

1.2 It's difficult to do good research

Simply trying something and seeing what happens, like my children do, is a research method that relies on luck and chance. Before I go into more grown-up ways of doing research, I want to emphasize that the role of chance and serendipity in research is often downplayed and not acknowledged. The most well-known example of such research is the discovery of penicillin by Alexander Fleming. In 1928, Fleming was studying the properties of staphylococcus bacteria when he noticed that a mold called *Penicillium notatum* had contaminated one of his bacterial cultures. He noticed that the mold seemed to be inhibiting the growth of the bacteria, and he began to investigate this further. Eventually, he was able to isolate and purify the active ingredient in the mold, which he named penicillin, and he discovered that it had powerful antibiotic properties. This discovery revolutionized the field of medicine and has saved countless lives.

Doing something on purpose and observing how things respond to the action can be considered a research strategy. Acting like a child or just waiting for something to happen by chance can also be considered a research strategy, and of course this can contribute greatly to knowledge. However, it are a naïve and poorly targeted strategies to conduct research. There are more grown-up research methods that are targeting more precisely the gaps in our knowledge and speed up innovation in the field where progress is desperately needed.

⁶Freely quoted (and translated) from Weymar (1955, p. 521)

⁷Photography is public domain and stems from https://en.wikipedia.org/wiki/File:Synthetic_Production_of_Penicillin_TR1468.jpg

Figure 1.6: Sir Alexander Fleming (1881-1955)⁷

What we do and how we observe what is happening should be done in a way to increase the likeliness that we find something new and interesting and in a way that allows us to be rather certain that our results are true and are less likely to be falsified soon later.

For example, assume that there is a disease that can kill people. The childish way to figure out how to cure the disease would be to observe who gets sick and who dies, and finally hope to find a cure for the disease by accidental observation. This is most likely not a very promising and quick method. It would probably be much better to study the matter systematically. For example, a laboratory should first seek to isolate the causative virus or bacterium in order to be able to grow and study it outside the danger to humans. Once this is done, we need a precise plan on how we can use all the available knowledge to cure the disease, protect people from infection, or help them survive the disease. In short, we need a strategic way to conduct research, i.e., a research strategy or design.

A *research strategy* is a general plan for conducting a study and a *research design* is a detailed plan for conducting the study. These words are frequently used interchangeably. A research strategy depends on many things including the question, the resources available, the current state of knowledge, the ambitions, whether quantitative or qualitative data are used, and what is considered to be the criteria of good research.

Before discussing some research strategies that can provide reasonable answers to certain types of questions, we should clarify how to ask a research question and what qualifies a research question.

1.3 Asking questions like a good researcher

Unfortunately, there is no one research strategy that is appropriate for all questions and, what is worse, there is still controversy about what constitutes good research and how to properly ask a research question. In particular, this controversy takes place between researchers who use quantitative data and statistical methods and researchers who use qualitative data and methods.

Quantitative researchers are more interested in determining the causes of effects using experiments with measurable results, and they attempt to quantify the effects of causes. Qualitative researchers also try to determine the causes of effects. However, their data analysis does rely less on statistical inference. A qualitative data set not necessarily requires (large) random samples or structured data (all the data that you can structure in a spreadsheet) in general, but allows to analyze selective and unstructured data (that is data in form of audio, video, text, images and alike). Qualitative research methods allow to classify these data into patterns or to interpret them in a meaningful way in order to arrive at results. Qualitative researchers are more concerned with the *why and how* of decision making and examine people's behavior, beliefs, perceptions of events, experiences, attitudes, interactions, and more in great depth.

In empirical research, inductive and deductive are two different approaches to reasoning. *Inductive reasoning* is a process of collecting data from various sources, such as interviews, surveys or observations, and then use this data to identify patterns, themes, or relationships that can form the basis of a new hypothesis or theory. The goal of these exploratory studies, is to generate new ideas or insights about a topic, rather than testing a specific hypothesis. *Deductive reasoning* is a process in which the researcher starts with a general theory or hypothesis with the goal to test a specific hypothesis or theory. In most cases, a combination of both inductive and deductive reasoning may be used to formulate the research question and to design the empirical identification strategy.

In what follows, however, we focus on the criteria for *good research* that are more commonly used in evaluating the quality of quantitative research.

Exercise 1.1. The Effect ch.1+2

Read chapter 1 and 2 of Huntington-Klein (2022) and answer the questions below. The book is freely available at <https://theeffectbook.net> and here is the link to chapter 1: <https://theeffectbook.net/ch-TheDesignofResearch.html>

1. What is the main focus of the book the author is writing about?
 - a) Philosophy of science

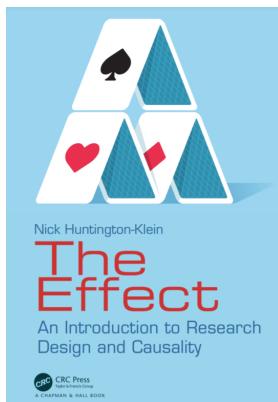

Figure 1.7: The book *The Effect: An Introduction to Research Design and Causality* by Nick Huntington-Klein (2022).

- b) Qualitative research methods
 - c) Empirical research and quantitative methods to identify and measure causal effects
 - d) Statistics
2. What is the main challenge faced by quantitative empirical research, according to the author?
 - a) Difficulty in obtaining accurate measurements
 - b) Difficulty in interpreting measurements
 - c) Difficulty in obtaining data that allows to answers the research question
 - d) Difficulty in designing a research that gets a lot of attention
 3. What is the author's main point about research questions?
 - a) They should be well-defined, answerable, and understandable
 - b) They should be simple and easy to answer
 - c) They should be related to the world of traffic
 - d) They should be related to the field of quantum mechanics

Please find solution to the exercise [in the appendix](#).

1.4 Features of good research

In order to make you a competent researcher who does not have to wait for a lucky chance but has a clear strategy, let's discuss the criteria of a good research. Before

I do that, however, I must make a disclaimer: there is a lack of consensus on what constitutes high-quality research in social sciences. In my experience, the practical benefits of such a tedious discussion are quite small. All I like to put forward is that I believe that all social science disciplines such as sociology, anthropology, psychology, economics, business administration, and education using quantitative methods agree that good research should be replicable, reproducible, transparent, reliable, and valid.

1.4.1 Reliability and validity

A research design is a plan to examine information in a systematic and controlled way so that the results of the research are *valid and reliable*.

Validity refers to the accuracy and truthfulness of research findings. In other words, if a study is valid, it should measure what it is intended to measure and produce results that are representative of the population being studied. Validity is important because it helps to ensure that the conclusions drawn from a study are supported by the data and are not based on flawed or biased methods.

Reliability refers to the consistency and stability of research findings. In other words, if a study is reliable, it should produce similar results if it is repeated using the same methods and conditions. Reliability is important because it helps to ensure that the results of a study are not simply due to chance or random error.

Both reliability and validity are important considerations in research, and researchers strive to maximize both in their studies. However, it is important to note that it is often difficult to achieve both at the same time, and trade-offs may need to be made between the two.

Statement: A good research design should aim to minimize bias and maximize the reliability and validity of the research. It should also be appropriate for the research question being asked and the resources available to the researcher.

High reliability and low validity

An example of a study that has high reliability but low validity is a study that measures the weight of a group of people using a digital scale. If the scale is consistently accurate and produces the same weight measurements each time it is used, then the study has high reliability. However, if the scale is not calibrated correctly and produces inaccurate weight measurements, then the study has low validity.

Another example of a research design that has high reliability but low validity is a study that uses a highly reliable measurement tool, such as a standardized test, to measure a concept that is not directly related to the research question being asked. For example, a study that uses a standardized math test to measure students' critical thinking skills may have high reliability because the test is consistently accurate and produces similar scores each time it is administered. However, the study may have low validity because the math test is not an appropriate tool for measuring critical thinking skills. As a result, the results of the study may not be representative of the students' true critical thinking abilities.

High validity and low reliability

An example of a study that has high validity but low reliability is a study that asks people to self-report their eating habits. While the study may produce accurate and representative results about people's eating habits, the self-reported data may vary from person to person and may not be consistent over time. As a result, the study has high validity but low reliability.

Another example of a study that has high validity but low reliability is a study that uses a highly valid measurement tool, such as a survey, to measure a concept that is directly related to the research question being asked. However, the study may have low reliability because the survey is not administered consistently or the responses are not accurately recorded. For example, a study that uses a survey to measure students' attitudes towards school may have high validity because the survey is relevant to the research question and accurately measures the students' attitudes. However, if the survey is not administered consistently or the responses are not accurately recorded, the study may have low reliability. As a result, the results of the study may not be representative of the students' true attitudes towards school.

Trade-offs between reliability and validity

In research design, trade-offs may need to be made between reliability and validity. For example, a study that uses a highly reliable measurement tool may not be valid if the tool is not appropriate for the research question being asked. Similarly, a study that uses a highly valid measurement tool may not be reliable if the tool is prone to producing inconsistent results. As a result, researchers must carefully consider both reliability and validity when designing a study and make trade-offs as necessary to maximize the overall quality of the research.

1.4.2 Generalizability

Coming back to my little son who threw everything within reach to the ground and giggled with joy at the clink he made when the object hit the ground. He identified a cause-and-effect relationship through an experiment in a controlled environment. His law “I throw something off the table and it always clangs” worked in our home. To our regret, it was replicable and he really tried hard to falsify it. Moreover, his study was reasonably valid as his study design, conduct, and analysis could answer his research questions without bias (at least ignoring the other noises that his sibling and parents make coincidentally during his experiment). Scientist call this *internal validity*. However, he also found out that when he leaves our home, things are sometimes a bit different, for example, if there is a carpet under the table. Thus, his insights from our home findings can’t be generalized to other contexts, at least not without further specifications. Scientist call this *external validity*.

Statement: Internal validity examines whether the study design, conduct, and analysis answer the research questions without bias. External validity examines whether the study findings can be generalized to other contexts.

1.4.3 Replicability, reproducibility, transparency, and other criteria

It must be possible to repeat the research conducted for several reasons. For example, if you can repeat a study with slightly changed parameters, you are able to improve its external validity and show that the conclusions drawn are reliable. To be able to repeat a study, everything that is important for drawing a conclusion from the research has to be mentioned. This is what we call *transparency*. Moreover, everything in the study must have been done in such a way that we can check the results for truth. In the best case, it is possible to *reproduce* the results in the same way they were obtained in the study. Sometimes this is not possible because, for example, we can never really ask the same people again in a survey, and even if we found the same people, they would have gotten older and not be the same people as before. In such a case, it should at least be possible to *replicate* the research. This means that we can basically do the same thing in a setting that differs only in those things that we cannot avoid to be different. For example, by interviewing a group of people who match the people in the study to replicate them on all the important characteristics like age.

In an empirical quantitative research study, for example, the data and the code written to process the data and analyze it should be accessible to everyone.

In a qualitative study, all sources of information should be stated, and the circumstances leading to a conclusion should be fully explained. For example, all transcripts of interviews conducted should be made available. The researcher should provide rich and detailed descriptions of the data and the context in which it was collected. Research should be provided with rich, nuanced, and multi-layered accounts of social phenomena by describing and interpreting the meanings, beliefs, and practices of the people being studied. That is known as *thick description*. Researchers typically employ a variety of methods such as participant observation, in-depth interviews, and document analysis, and they often use multiple sources of data to triangulate their findings. The goal is to provide a holistic and broad understanding of the phenomenon being studied, rather than a narrow view from the researcher's perspective.

There are some other criteria of good research that are worth mentioning:

Credibility

The research should be trustworthy and believable, and the researcher should provide detailed descriptions of the methods used to ensure transparency.

Reflective Practice

The researcher should engage in reflexive practice throughout the research process, which means to be critically aware of oneself, one's own assumptions, and one's own role in the research process.

Triangulation

The researcher should use multiple methods, sources, and perspectives to increase the credibility of the findings (also see *thick description* above).

Transferability

The conclusions drawn from looking at mostly unstructured data in qualitative research can hardly be generalized in a strict sense, as they depend crucially on the context of the object of study. For example, generalizability is essentially impossible in a qualitative case study, since everything depends on the specific situation of an individual, a company, or a group of people considered in the specific setting. This means that in a case study or interview, we may be looking

at only a few or even a single observation that cannot be considered *representative* of the larger population, as generalizability does. Transferability, on the other hand, gives the reader the ability to transfer the findings into other contexts. The ability to transfer contextual findings to other cases is a goal of qualitative research, and the author of a study should attempt to offer the information in a way that allows the reader to transfer the findings to the setting or situation with which he or she is familiar.

1.5 The role of resources, data and ethics

There are several types of research designs, including experimental designs, quasi-experimental designs, and observational designs. Each of these designs took advantage of various empirical methods and statistical procedures. We will discuss some of them later on. The choice of research design, of course, should depend on the research question being asked, the resources available, and the type of data that is being collected. The research design should also take into account any ethical considerations that may be relevant to the research. The research design should be chosen so that it is well suited to answer the research question. For example, if one is interested in the question “Why do some people get sick with a certain disease and others do not?” then an observational study design to determine possible *causes of effect* may be appropriate. These identified potential causes should then be verified followed by an experimental study. Relatively, a statistical analysis should be used which would allow the *effects of causes* to be evaluated. The aim should be to identify necessary and sufficient circumstances to develop a disease. Also circumstances should be described that favor a disease.

If the question is a “how” question, for example, “How do parents feel when their child throws everything off the table?” then interviews might be an appropriate study design. If available resources such as time, funding, and staff are limited, you might also consider conducting an (online) survey in which parents are asked standardized questions about their feelings. In any way, the chosen research design must be feasible given the resources available.

In answering a question, a researcher should know, state, and discuss all the assumptions and unexamined beliefs that led him to his conclusion. However, since resources for conducting and explaining research are limited, special attention should be paid to what are called *critical assumptions*. These are assumptions that must be true in reality, otherwise the research is meaningless. Therefore, researchers should make great efforts to identify and validate these assumptions.

The type of data that is being collected is another important factor to consider

when choosing a research design. Different types of data, such as quantitative data, qualitative data, or a combination of both, may require different methods of collection and analysis. For example, quantitative data, such as numerical data, can be collected through methods such as surveys and analyzed using statistical techniques, whereas qualitative data, such as interview transcripts, may require more interpretive methods of analysis.

Finally, the researcher should also take into account any ethical considerations that may be relevant to the research. For example, if the study involves human subjects, the researcher must ensure that the study is conducted in accordance with ethical principles such as informed consent and confidentiality. Additionally, the researcher should ensure that the potential benefits of the study outweigh any potential risks to the subjects.

Exercise 1.2. Features of research

1. Which of the following best defines reliability in research?
 - a) The extent to which a measurement tool produces consistent results
 - b) The extent to which a study's results accurately reflect the concept being measured
 - c) The extent to which a study's results can be generalized to other populations
 - d) The extent to which a study's results are statistically significant
2. Which of the following best defines validity in research?
 - a) The extent to which a measurement tool produces consistent results
 - b) The extent to which a study's results accurately reflect the concept being measured
 - c) The extent to which a study's results can be generalized to other populations
 - d) The extent to which a study's results are statistically significant
3. Which of the following is an example of a study with high reliability but low validity?
 - a) A study that uses a highly reliable measurement tool to measure a concept that is directly related to the research question being asked
 - b) A study that uses a highly valid measurement tool to measure a concept that is not directly related to the research question being asked
 - c) A study that uses a highly reliable measurement tool to measure a concept that is not directly related to the research question being asked

- d) A study that uses a highly valid measurement tool to measure a concept that is directly related to the research question being asked
4. Which of the following is an example of a study with high validity but low reliability?
- A study that uses a highly reliable measurement tool to measure a concept that is directly related to the research question being asked
 - A study that uses a highly valid measurement tool to measure a concept that is not directly related to the research question being asked
 - A study that uses a highly reliable measurement tool to measure a concept that is not directly related to the research question being asked
 - A study that uses a highly valid measurement tool to measure a concept that is directly related to the research question being asked
5. What does internal validity examine in a study?
- The ability to replicate the study
 - The generalizability of the study's findings
 - Whether the study design, conduct, and analysis answer the research questions without bias
 - All of the above
6. What does external validity examine in a study?
- The ability to replicate the study
 - The generalizability of the study's findings
 - Whether the study design, conduct, and analysis answer the research questions without bias
 - None of the above
7. What is transparency in research?
- The ability to replicate a study
 - The generalizability of the study's findings
 - The availability and accessibility of the data and materials used in a study for others to review
 - The ethical considerations of the research
8. What are the different types of research design discussed in the text?
- Experimental designs, quasi-experimental designs, and observational designs
 - Experimental designs and descriptive designs
 - Quasi-experimental designs and observational designs

- d) None of the above
9. Why is replicability important in a study?
- To be able to repeat a study with slightly changed parameters and thus improve the external validity
 - To be able to check the results of the study for truth.
 - To be able to reproduce the results in the same way they were obtained in the study
 - All of the above

Please find solution to the exercise [in the appendix](#).

Glossary

- **Generalizability:** The extent to which the results of a study can be applied to other populations or contexts.
- **Internal validity:** The degree to which a study's results can be attributed to the specific variables or factors being studied, and not to other extraneous factors.
- **External validity:** The degree to which a study's results can be generalized to other populations or contexts outside of the specific sample or setting of the study.
- **Quantitative data:** Data that can be measured and quantified.
- **Qualitative data:** Data that cannot be easily measured or quantified.
- **Quantitative research:** A research approach that uses statistical methods and experiments to determine the causes of effects, to quantify the effects of causes, or to describe data.
- **Qualitative research:** A research approach that uses unstructured data and methods to examine, for example, people's behavior, beliefs, and experiences in depth, rather than quantifying results.
- **Reflective Practice:** A form of self-evaluation used to analyze one's own thoughts and actions.
- **Reliability:** The consistency of a study's results to produce similar results when repeated.
- **Research design:** A detailed plan for conducting a study, frequently used interchangeably with research strategy.
- **Research method:** A procedure used to conduct a study or investigation to gain knowledge or understanding about a particular topic.

- **Research question:** A question or problem that a study aims to answer or solve.
- **Research strategy:** A general plan for conducting a study, frequently used interchangeably with research design.
- **Replicability:** The ability of a study to be repeated with new data.
- **Reproducibility:** The ability of a study to be repeated and produce the same results, often used interchangeably with replicability.
- **Serendipity:** The role of luck and unexpected events in research.
- **Thick Description:** A detailed narrative used to explain a situation and its context.
- **Credibility:** A quality criterion in qualitative research, which refers to confidence in the truth value of the data and interpretations of them.
- **Transparency:** The degree to which a study's methods and data are easily accessible and understandable to others, allowing for the study to be independently evaluated and replicated.
- **Triangulation:** A method used in qualitative research to verify the accuracy of data by combining multiple sources of information.
- **Validity:** The degree to which a study measures what it is intended to measure, and the extent to which the results of the study can be considered accurate and meaningful.
- **Structured data:** Data that can be easily organized and analyzed in a structured format, such as a spreadsheet.
- **Unstructured data:** Data that cannot be easily organized and analyzed in a structured format, such as text, images, and audio.

Chapter 2

Identification

In empirical research, *identification* refers to the process of establishing a clear and logical relationship between a cause and an effect. This involves demonstrating that the cause is responsible for the observed effect, and that there are no other factors that could potentially explain the effect. The goal of identification is to provide strong evidence that a particular factor is indeed the cause of a particular outcome, rather than simply coincidentally happen. In order to identify a cause-and-effect relationship, researchers can use experimental or non-experimental, i.e., observational data, or both. The next section discusses how to generate or collect this data.

2.1 How to get data

There are several ways to get data which allows you to identify a cause-and-effect relationship:

2.1.1 Interviews

An interview is normally a one-on-one verbal conversation. Interviews are conducted to learn about the participants' experiences, perceptions, opinions, or motivations. The relationship between the interviewer and interviewee must be taken into account and other circumstances (place, time, face to face, email, etc.)

¹The picture is free to use under the Pixabay license, see: [https://pixabay.com/images/
id-4799256/](https://pixabay.com/images/id-4799256/)

Figure 2.1: Interview¹

should be taken into account. There are three types of interviews structured, semi-structured, and unstructured. *Structured interviews* use a set list of questions and hence are like a verbal surveys. In *unstructured interviews* the interviewer doesn't use predetermined questions but only a list of topics to address. Semi-structured interviews are the middle ground. Semi-structured interviews require the interviewer to have a list of questions and topics pre-prepared, which can be asked in different ways with different interviewee/s. Semi-structured interviews increase the flexibility and the responsiveness of the interview while keeping the interview on track, increasing the reliability and credibility of the data. Semi-structured interviews are one of the most common interview techniques.

Structured interviews use a predetermined list of questions that must be asked in a specific order, improving the validity and trustworthiness of the data but lowering respondent response. Structured interviews resemble verbal questionnaires. In unstructured interviews, the interviewer has a planned list of subjects to cover but no predetermined interview questions. In exchange for less reliable data, this makes the interview more adaptable. Long-term field observation studies may employ unstructured interviews. The middle ground are interviews that are semi-structured. In semi-structured interviews, the interviewer must prepare a list of questions and themes that can be brought up in various ways with various interviewees.

Interviews allow you to address a cause-and-effect relationship fairly directly, and it can be a good idea to interview experts and ask some *why* and *how* questions to gather initial knowledge about a particular topic before further elaborating your research strategy. For example, I interviewed kindergarten teachers with many years of experience working with children, as well as other parents, to get information on how to solve the problem of my children throwing plates around the dining room. However, findings based on interviews are not very valid or reliable because the personal perceptions of both the interviewer and the interviewee can have an impact on the conclusions drawn. For example, I received very different tips and explanations because of the personal experiences of the people I interviewed. Unfortunately, I could not really ask my son why he was misbehaving.

His vocabulary was too limited at the time, and even if he could speak, he would probably refuse to tell me the truth.

2.1.2 Surveys

Figure 2.2: Survey²

In contrast to an interview a survey can be sent out to many different people. Surveys can be used to identify a cause-and-effect relationship by asking questions about both the cause and the effect and examining the responses. For example, if a researcher wanted to determine whether there is a relationship between a person's level of education and their income, they could conduct a survey asking participants about their education level and their income. If the data shows that participants with higher levels of education tend to have higher incomes, it suggests that education may be a cause of higher income. However, it is important to note that surveys can only establish a correlation between variables, but it is difficult to claim that correlations found through the survey imply a causal relationship. To establish a causal relationship, a researcher would need to use other methods, such as an experiment, to control for other potential factors that might influence the relationship that the respondent does not see.

2.1.3 Case studies

Figure 2.3: Case study³

²The picture is free to use under the Pixabay license, see: [https://pixabay.com/images/
id-1594962/](https://pixabay.com/images/id-1594962/)

Case studies involve in-depth examination of a single case or a small number of cases in order to understand a particular phenomenon. Case studies can be conducted using both quantitative and qualitative methods, depending on the research question and the data being analyzed. While it is reasonable to find causal effects in the particular case, it is problematic to generalize the causal relationship. To establish a general causal relationship, a researcher would need to use other methods, such as an experiment, to control for other potential factors that might influence the relationship that the respondent does not see.

2.1.4 Experiments

One way to clearly identify a cause-and-effect relationship is through experiments, which involve manipulating the cause (the independent variable) and measuring the effect (the dependent variable) under controlled conditions (we will later on define precisely what is meant here). Experiments can be conducted using both quantitative and qualitative methods. Here are some examples:

- A medical study in which a new drug is tested on a group of patients, while a control group receives a placebo.
- An educational study in which a group of students is taught a new method of learning, while a control group is taught using the traditional method.
- An agricultural study in which a group of crops is treated with a new fertilization method, while a control group is not treated.
- A study to determine the effect of a new training program on employee productivity might involve randomly assigning employees to either a control group that does not receive the training, or an experimental group that does receive the training. By comparing the productivity of the two groups, the researchers can determine if the new training program had a causal effect on employee productivity.
- A study to determine the effect of a new advertising campaign on sales might involve randomly assigning different groups of customers to be exposed to different versions of the campaign. By comparing the sales of the different groups, the researchers can determine if the advertising campaign had a causal effect on sales.
- In *experimental economics*, experimental methods are used to study economic questions. In a lab-like environment data are collected to investigate the size of certain effects, to test the validity of economic theories, to illuminate

³Picture is free to use and stems from RODNAE Productions and was taken from Pexels:
<https://www.pexels.com/de-de/foto/linse-geschaft-papier-aufsicht-7947753/>

market mechanisms, or to examine the decision making of people. Economic experiments usually motivates and rewards subjects with money. The overall goal is to mimic real-world incentives and investigate things that cannot be captured or identified in the field.

- In *behavioral economics*, laboratory experiments are also used to study decisions of individuals or institutions and to test economic theory. However, it is done with a focus on cognitive, psychological, emotional, cultural, and social factors.

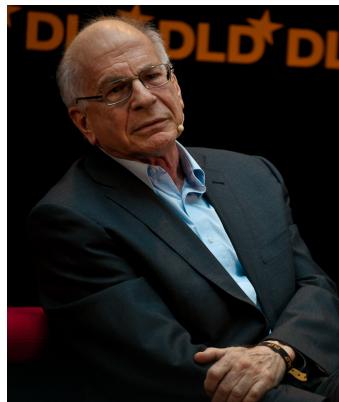

Figure 2.4: Daniel Kahneman (*1934)⁴

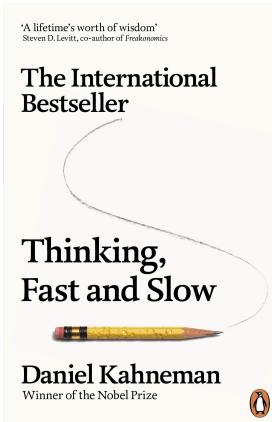

Figure 2.5: Kahneman (2011): Thinking, Fast and Slow

In 2002 the Nobel Prize of Economics was awarded to Vernon L. Smith “for having established *laboratory experiments* as a tool in empirical economic analysis,

⁴The picture of Kahneman is free to use and stems from [https://commons.wikimedia.org/wiki/File:Daniel_Kahneman_\(3283955327\)_cropped.jpg](https://commons.wikimedia.org/wiki/File:Daniel_Kahneman_(3283955327)_cropped.jpg)

especially in the study of alternative market mechanisms” ([The Royal Swedish Academy of Sciences, 2002](#)) and Daniel Kahneman “for having integrated insights from psychological research into economic science, especially concerning human judgment and decision-making under uncertainty” ([The Royal Swedish Academy of Sciences, 2002](#)).

The strength of evidence from a controlled experiment is generally considered to be strong. However, the external validity, i.e., the generalizability, should be considered as well. External validity is sometimes low because effects that you can identify and measure in a lab are sometimes only of minor importance in the field.

There are different types of experiments:

Randomized controlled trials (RCTs) are a specific type of an experiment that involve randomly assigning participants to different treatment groups and comparing the outcomes of those groups. RCTs are often considered the gold standard of experimental research because they provide a high degree of control over extraneous variables and are less prone to bias.

For a better explanation and some great insights into what an RCT actually is, please watch the video produced by UNICEFInnocenti and published on the YouTube channel of UNICEF’s dedicated research center <https://youtu.be/Wy7qpJeozec>

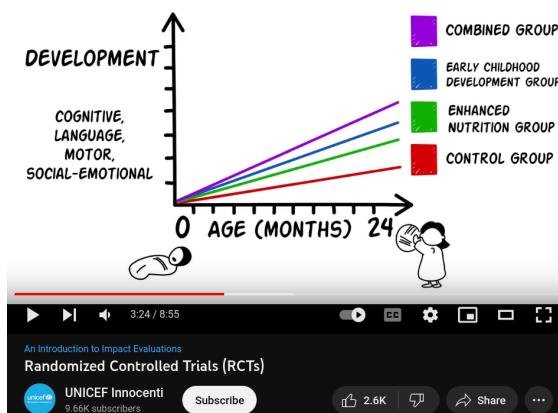

Figure 2.6: Randomized Controlled Trials (RCTs)

Quasi-experiments involve the manipulation of an independent variable, but do not involve random assignment of participants to treatment groups. Quasi-experiments are less controlled than RCTs, but can still provide valuable insights into cause-and-effect relationships.

Natural experiments involve the observation of naturally occurring events or situations that provide an opportunity to study cause-and-effect relationships. Nat-

ural experiments are often used when it is not possible or ethical to manipulate variables experimentally.

In a **laboratory experiment**, researchers manipulate an independent variable and measure the effect on a dependent variable in a controlled laboratory setting. This allows for greater control over extraneous variables, but the results may not generalize to real-world situations.

In a **field experiment**, researchers manipulate an independent variable and measure the effect on a dependent variable in a natural setting, rather than in a laboratory. This allows researchers to study real-world phenomena, but it can be more difficult to control for extraneous variables.

2.1.5 Observational data

Figure 2.7: Observational data⁵

Observational data are data that had been observed before the research question was asked or being collected independently from the study. To understand how observational data can be used to constitute a causal relationship is a bit tricky because there is only one world and only one reality at a time. In other words, we usually miss a counterfactual which we can use for a comparison. Take, for example, the past COVID-19 pandemic, where you chose to be vaccinated or not. Regardless of what you chose, we will never find out what would have happened to you if you had chosen differently. Maybe you would have died, maybe you would have gotten more or less sick, or maybe you wouldn't have gotten sick at all. We don't know, and it's impossible to find out because it's impossible to observe the counterfactual outcomes. This makes it difficult to establish causality from observational data. However, ingenious minds have found reasonable procedures and methods to extract some level of knowledge from observational data that allows us to infer causal relationships from observational data where we cannot directly observe the counterfactual outcome. We will come back to these methods later on.

⁵The picture is free to use under the Pixabay license, see: [https://pixabay.com/images/
id-5029286/](https://pixabay.com/images/id-5029286/)

In the upcoming sections, however, we will discuss experimental research designs including *randomized controlled trials* (RCTs) which are considered to be the “gold standard for measuring the effect of an action” (Taddy, 2019, p. 128). RCTs can be used, for example, to study the effectiveness of drugs by observing people randomly assigned to three groups, one taking the pill (or treatment), a second receiving a placebo, and a third taking nothing. If the first group responds in any way differently than the other groups, the drug has an effect. Before explaining an RCT in more detail, we need to be clear about the fundamental problem of causal inference. This will be discussed in the following.

Exercise 2.1. Methods used in economic research

Read Paldam (2021) which is freely available, see <https://doi.org/10.1515/econ-2021-0003> and answer the following questions:

- a) List the eight types of research methods described in the paper and provide the description found in the paper.
- b) Read the following statements and discuss whether they are true or not, and if the latter, correct them:
 - i) The annual production of research papers in economics in the year 2017 has reached about 100 papers in top journals, and about 1,400 papers in the group of good journals. The production has grown with 3.3% per year, and thus it has doubled the last twenty years.
 - ii) The upward trend in publication must be due to the large increase in the importance of publications for the careers of researchers, which has greatly increased the production of papers. There has also been a large increase in the number of researches, but as citations are increasingly skewed toward the top journals it has not increased demand for papers correspondingly.
 - iii) Four trends are significant: The fall in theoretical papers and the rise in classical papers. There is also a rise in the share of statistical method and event studies. It is surprising that there is no trend in the number of experimental studies.
 - iv) Book reviews have dropped to less than 1/3. Perhaps, it also indicates that economists read fewer books than they used to. Journals have increasingly come to use smaller fonts and larger pages, allowing more words per page. The journals from North-Holland Elsevier have managed to cram almost two old pages into one new one. This makes it easier to publish papers, while they become harder to read.
 - v) About 50% of papers in the sample considered in Paldam (2021) belong to the economic theory class, about 6% are experimental studies, and about 43% are empirical studies based on data inference.

- vi) The papers in economic theory have increased from 33.6% to 59.5% – this is the largest change for any of the eight subgroups. It is highly significant in the trend test.
- c) Explain what is meant with *theory fatigue* and discuss the reasons that lead to that fatigue.
- d) What makes according to Paldam (2021) research papers relevant for policymakers right from the start?

Please find solution to the exercise [here](#).

Solution to exercise 2.1: Methods used in economic research

- a)
- 1. **Economic theory:** Papers are where the main content is the development of a theoretical model. The ideal theory paper presents a (simple) new model that recasts the way we look at something important.
- 2. **Statistical technique, incl. forecasting** Papers reporting new estimators and tests are published in a handful of specialized journals in econometrics and mathematical statistics. Some papers compare estimators on actual data sets. If the demonstration of a methodological improvement is the main feature of the paper, it belongs to this subgroup, but if the economic interpretation is the main point of the paper, it belongs to the classical empirical studies or newer techniques group.
- 3. **Surveys, incl. meta-studies** When the literature in a certain field becomes substantial, it normally presents a motley picture with an amazing variation, especially when different schools exist in the field. They are of two types, where the second type is still rare:
 - Firstly, assessed surveys where the author reads the papers and assesses what the most reliable results are. Such assessments require judgment that is often quite difficult to distinguish from priors, even for the author of the survey.
 - Secondly, meta-studies which are quantitative surveys of estimates of parameters claimed to be the same. These types of studies have two levels: The basic level collects and codes the estimates and studies their distribution. This is a rather objective exercise where results seem to replicate rather well. The second level analyzes the variation between the results. This is less objective.

4. **Experiments in laboratories** Most of these experiments take place in a laboratory, where the subjects communicate with a computer, giving a controlled, but artificial, environment. A number of subjects are told a (more or less abstract) story and paid to react in either of a number of possible ways. A great deal of ingenuity has gone into the construction of such experiments and in the methods used to analyze the results. Lab experiments do allow studies of behavior that are hard to analyze in any other way, and they frequently show sides of human behavior that are difficult to rationalize by economic theory. However, everything is artificial – even the payment while participants usually receive real money for participation and their performance. In some cases, the stories told are so elaborate and abstract that framing must be a substantial risk. In addition, experiments cost money, which limits the number of subjects. It is also worth pointing to the difference between expressive and real behavior. It is typically much cheaper for the subject to ‘express’ nice behavior in a lab than to be nice in the real world.
5. **Event studies (field experiments and natural experiments)** Event studies are studies of real world experiments. They are of two types:
 - Firstly, **field experiments** analyze cases where some people get a certain treatment and others do not. The ‘gold standard’ for such experiments is double blind random sampling, where everything (but the result!) is announced in advance. Experiments with humans require permission from the relevant authorities, and the experiment takes time too. In the process, things may happen that compromise the strict rules of the standard. Controlled experiments are expensive, as they require a team of researchers.
 - Secondly, **natural experiments** take advantage of a discontinuity in the environment, i.e., the period before and after an (unpredicted) change of a law, an earth-quake, etc. Methods have been developed to find the effect of the discontinuity. Often, such studies look like classical empirical studies with many controls that may that may or may not belong. Thus, the problems discussed under the classic empirical studies also apply here.
6. **Descriptive, deductions from data** In a descriptive study, researcher use an existing sample and hence, they have no control over the data generating process as it is usually the case with experiments. Descriptive studies are deductive. The researcher describes the data aiming at finding structures that tell a story, which can be interpreted. The findings may call for a formal test. If one clean test follows from the description, the paper can still be classified as a descriptive study. If more elaborate regression analysis is used,

however, it can also be classified as a classical empirical study. Descriptive studies often contain a great deal of theory. Some descriptive studies present a new data set developed by the author to analyze a debated issue. In these cases, it is often possible to make a clean test, so to the extent that biases sneak in, they are hidden in the details of the assessments made when the data are compiled.

7. **Classical empirical studies** Typically have three steps: It starts by a theory, which is developed into an operational model. Then it presents the data set, and finally it runs regressions. The significance levels of the t-ratios on the coefficient estimated assume that the regression is the first meeting of the estimation model and the data. In practice, we all know that this is rarely the case. The classical method is often just a presentation technique. The great virtue of the method is that it can be applied to real problems outside academia. The relevance comes with a price: The method is quite flexible as many choices have to be made, and they often give different results. Preferences and interests, may affect these choices.
8. **Newer techniques** Partly as a reaction to the problems of classical empirical methods, the last 3–4 decades have seen a whole set of newer empirical techniques. They include different types of vector autoregression (VAR)⁶, Bayesian techniques, causality and co-integration tests, Kalman filters, hazard functions, etc. The main reason for the lack of success for the new empirics is that it is quite bulky to report a careful set of co-integration tests or VARs, for example, and they often show results that are far from useful in the sense that they are unclear and difficult to interpret.

b) Solutions to b)

- i) The annual production of research papers in economics in the year 2017 has now reached about **1,000** papers in top journals, and about **14,000** papers in the group of good journals. The production has grown with 3.3% per year, and thus it has doubled the last twenty years.
- ii) Statement is correct.
- iii) Statement is correct.
- iv) Statement is correct.

⁶A VAR is a statistical model used to capture the relationship between multiple quantities as they change over time.

- v) Statement is correct.
 - vi) The papers in economic theory have **dropped from 59.5% to 33.6%** – this is the largest change for any of the eight subgroups. It is highly significant in the trend test.
- c) Theory fatigue simply explains the declining attractiveness of theoretical research for journals, researchers, and policymakers that can be justified or accompanied by an increasing importance of empirical research. Variations of existing theoretical models are more difficult to sell to policymakers and it is hard for researchers to summarize the knowledge of theoretical papers in a systematic way and to conclude on a certain topic. Moreover, theoretical papers can be very unconvincing and can hardly be understood by a broader audience which has to grant that the calculations are done right. Often, believability hinges on the realism of the assumptions at the start and of the results presented at the end. In order for a model to convince, it should (at least) demonstrate the realism of either the assumptions or the outcome. If both ends appear to hang in the air, it becomes a game giving little new knowledge about the world. The theory fatigue has caused a demand for simulations demonstrating that the models can mimic something in the world. Calibrations may be carefully done, but it often appears like a numerical solution of a model that is too complex to allow an analytical solution. Thus, these calibrations cannot really solve the fatigue.
- d) The typical classical paper provides estimates of a key effect that decision-makers outside academia want to know. This makes the paper policy relevant right from the start, and in many cases, it is possible to write a one page executive summary to the said decision-makers.

2.2 Correlation does not imply causation

Correlation refers to a statistical relationship between two variables, where one variable tends to increase or decrease as the other variable also increases or decreases. However, just because two variables are correlated does not necessarily mean that one variable causes the other. This is known as the *correlation does not imply causation* principle.

For example, it may be observed that the number of storks in a particular area is correlated with the birth rate of babies in that area. However, this does not mean that the presence of storks causes an increase in the birth rate. It is possible that

both the number of storks and the number of babies born are influenced by other factors, such as the overall population density or economic conditions in the area.

Therefore, it is important to carefully consider all possible explanations (confounders) for a correlation and to use empirical evidence to determine the true cause-and-effect relationship between variables.

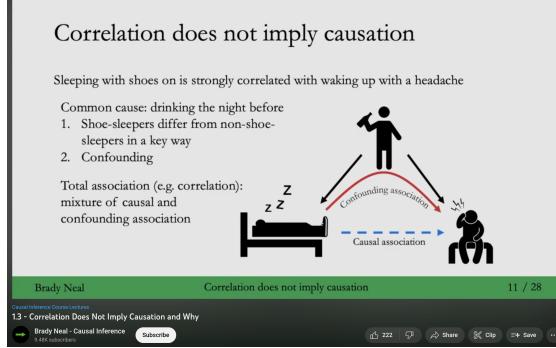

Figure 2.8: Correlation does not imply causation⁷

Watch Brady Neal's lecture on *Correlation Does Not Imply Causation and Why* which can be found here: https://youtu.be/DFPm_a-_uJM. Alternatively, you can read chapter 1.3 of his lecture notes (Neal, 2020) which you find here: https://www.bradyneal.com/Introduction_to_Causal_Inference-Dec17_2020-Neal.pdf.

2.3 The fundamental problem of causal inference

Figure 2.9: The book cover of “Causal Inference: The Mixtape?” by Scott Cunningham (2021)

Cunningham (2021, ch. 1.3): “*It is my firm belief, which I will emphasize over and over in this book, that without prior knowledge, estimated*

⁷Picture is taken from https://youtu.be/DFPm_a-_uJM

causal effects are rarely, if ever, believable. Prior knowledge is required in order to justify any claim of a causal finding. And economic theory also highlights why causal inference is necessarily a thorny task.”

As [Cunningham \(2021\)](#) explains in his book, it is very hard to claim causality. In the following section, I will paraphrase briefly two aspects why it is so difficult to claim to have found a causal effect. It is difficult to know how to use data properly and how to find or generate the right data. Therefore, I will discuss Simpson’s Paradox and the that gives an idea how difficult it is to analyze observational data meaningful and that we need to have a theory when looking on data and we should try to challenge the assumptions on which our theory is built on. After that I will briefly discuss

Exercise 2.2. Causal inference ch.1

Before going on with the content in these notes, please read chapter 1 (Introduction) of [Cunningham \(2021\)](#) and answer the following questions. The book is freely available (<https://mixtape.scunning.com/>) and the link to chapter 1 is <https://mixtape.scunning.com/01-introduction>.

1. What are some common misconceptions about causality that the author addresses in chapter 1?
2. What is the role of randomization in causal inference, as described in the book?

Please find solution to the exercise [in the appendix](#).

2.3.1 Simpsons Paradox

Figure 2.10: Discrimination⁸

Discrimination is bad. Whenever we see it, we should try to find ways to overcome it. De jure segregation mandated the separation of races by law is clearly discriminatory. Other forms of discrimination, however, are often more difficult to spot and as long we don't have good evidence for discrimination, we should not judge prematurely. That means we should be sure that we see an act of making unjustified distinctions between individuals based on some categories to which they belong or perceived to belong. For example, if men and women are treated differently without an acceptable reason, we consider it discriminative. For example, UC Berkeley was accused of discrimination in 1973 because it admitted only 35% of female applicants but 44% of male applicants overall. The difference was statistical significant. However, it turned out that the selection of students was not discriminative against women but agains men accordingly to [Bickel, Hammel, and O'Connell \(1975\)](#). Who conclude there was just a "tendency of women to apply to graduate departments that are more difficult for applicants of either sex to enter" ([Bickel et al., 1975](#), p. 403). Figure 2.11 taken from [Bickel et al. \(1975, page 403\)](#) visualizes this fact.

Here you can read the summary of their infamous study:

"Examination of aggregate data on graduate admissions to the University of California, Berkeley, for fall 1973 shows a clear but misleading pattern of bias against female applicants. Examination of the disaggregated data reveals few decision-making units that show statistically significant departures from expected frequencies of female admissions, and about as many units appear to favor women as to favor men. If the data are properly pooled, taking into account the autonomy of departmental decision making, thus correcting for the tendency of women to apply to graduate departments that are more difficult for applicants of either sex to enter, there is a small but statistically significant bias in favor of women. The graduate departments that are easier to enter tend to be those that require more mathematics in the undergraduate preparatory curriculum. The bias in the aggregated data stems not from any pattern of discrimination on the part of admissions committees, which seem quite fair on the whole, but apparently from prior screening at earlier levels of the educational system. Women are shunted by their socialization and education toward fields of graduate study that are generally more crowded, less productive of completed degrees, and less well funded, and that frequently offer poorer professional employment prospects."

⁸The photography is public domain and stems from the Library of Congress Prints and Photographs Division Washington, see: <http://hdl.loc.gov/loc.pnp/pp.print>.

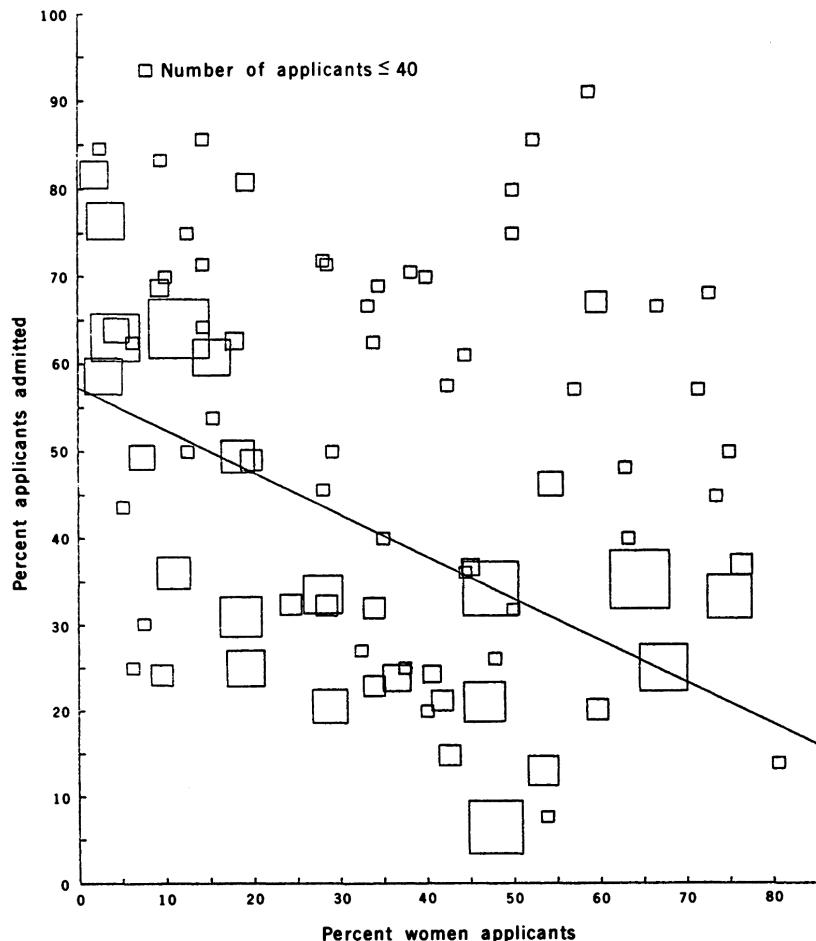

Fig. 1. Proportion of applicants that are women plotted against proportion of applicants admitted, in 85 departments. Size of box indicates relative number of applicants to the department.

Figure 2.11: Graph taken from [Bickel et al. \(1975, page 403\)](#)

Exercise 2.3. Graduate admissions

Read the first three pages of [Bickel et al. \(1975\)](#), i.e., pages 398-400, and answer the following questions. The article can be found here: <https://www.science.org/doi/pdf/10.1126/science.187.4175.398>.

- a) Describe the two assumptions that must be true in order to prove that UC Berkeley discriminates against women or men overall.
- b) Table 1, shows that 277 fewer women and 277 more men were admitted than we would have expected under the two assumptions. Show how this number was calculated.
- c) Explain the analogy with fish that illustrates the danger of pooling data.

Please find solution to the exercise [in the appendix](#).

Exercise 2.4. Simpson's Paradox

1. What is Simpson's Paradox?

- a) A phenomenon in which the direction of a relationship between two variables changes when a third variable is introduced
- b) A phenomenon in which the strength of a relationship between two variables changes when a third variable is introduced
- c) The phenomenon where correlation appears to be present in different groups of data, but disappears or reverses when the groups are combined

2. What is a potential cause of Simpson's Paradox?

- a) Differences in the variance of the two variables
- b) Differences in the correlation of the two variables
- c) Confounding variables
- d) Differences in the sample size of the two variables

2.3.2 Rubin causal model

[Keele \(2015\)](#), page 314): “*An identification analysis identifies the assumptions needed for statistical estimates to be given a causal interpretation.*”

If we are interested in the causal effect of a certain treatment on an outcome, we need to compare the outcome of the individuals who received the treatment to the outcome of the individuals who did not receive the treatment. However, if the counterfactual outcome is missing for some individuals, we cannot make this comparison and therefore cannot estimate the causal effect. Unfortunately, the counterfactual is very often missing. For example, if we want to measure the effect of a vaccine we never can have a person who is vaccinated and not vaccinated at the same time.

The Rubin Causal Model, also known as the potential outcomes framework, is a statistical framework for analyzing causality in the context of missing data. It goes back to Donald B. Rubin (*1943) a statistician and is now a widely used method for causal inference. The basic premise of the Rubin Causal Model is that for each individual in a study, there are two potential outcomes: the outcome that would occur if the individual were exposed to a certain treatment or intervention (the “treatment group”), and the outcome that would occur if the individual were not exposed to that treatment (the “control group”). The key idea is that these potential outcomes can be used to infer causality by comparing the outcomes between the treatment and control groups even if we do not have a full set of data.

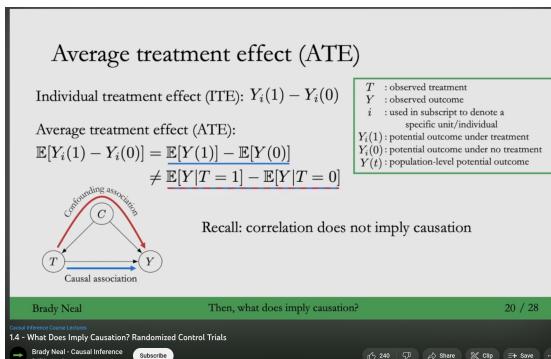

Figure 2.12: Average treatment effect (ATE)⁹

Watch Brady Neal's lecture on *What Does Imply Causation? Randomized Control Trials* which can be found here: <https://youtu.be/gGaWU8XEoGk>. Alternatively, you can read chapter 2 of his lecture notes (Neal, 2020) which you find https://www.bradyneal.com/Introduction_to_Causal_Inference-Dec17_2020-Neal.pdf.

Given the some assumptions, the Rubin Causal Model allows for estimation of the average treatment effect (ATE) - the difference in the expected outcomes between

⁹Picture is taken from <https://youtu.be/gGaWU8XEoGk>

the treatment and control groups. There are several ways to estimate the ATE under the Rubin Causal Model some of which will be part of this course. Applied correctly, it can provide valuable insights into causality and inform decision making. However, the Rubin Causal Model has its limitations and assumptions that need to be met in order for the inferences to be valid.

Exercise 2.5. Treatment effects

1. What is the individual treatment effect (ITE)?
2. What is the average treatment effect (ATE)?
3. How is the ATE calculated?
4. Can the ATE be used to determine the effect of a treatment on an individual level?
5. What are some potential sources of bias when estimating the ATE?

Please find solution to the exercise [in the appendix](#).

Chapter 3

Hands on experiments

3.1 Natural experiments

In social science, a *natural experiment* is a research design that exploits naturally occurring circumstances or events to study the effects of an intervention or treatment. In these experiments, the treatment is not manipulated by the researcher, but is instead determined by exogenous, or external, factors. *Exogenous variations* refer to changes in the independent variable that are not caused by the researcher's actions but instead occur naturally or through some external factor. These variations are often unpredictable and occur without the intervention of the researcher, making them an ideal source of variation to study the causal effects of a treatment or intervention. One example of a natural experiment is the partition of Germany after World War II, which created two economies that were initially similar but experienced vastly different economic and institutional environments. Another example is the introduction of a new policy or technology in one state or country but not in another, allowing for a comparison of outcomes before and after the treatment. A natural experiment might involve comparing the outcomes of two groups of people who were exposed to different levels of air pollution due to a policy change or a natural disaster. In this case, the variation in air pollution levels is exogenous, since it is not controlled by the researcher but rather determined by external factors.

By leveraging these exogenous variations, researchers can better estimate the causal effects of an intervention or treatment, and provide evidence for policymakers to make more informed decisions. In the following, we will get known to some studies that are based on natural experiments.

3.2 Empirical evidence: Bombing

In their article “Bones, Bombs, and Break Points: The Geography of Economic Activity,” [Davis and Weinstein \(2002\)](#) explore another natural experiment that has shaped the economic geography of the world: the natural endowment of different regions with physical and institutional factors that affect their productivity and attractiveness to economic activity. Using a spatial econometric model, they test the relative importance of three such factors: climate, natural resources, and political borders. They find that political borders, such as the ones that emerged from colonialism or ethnic conflict, have the strongest effect on economic activity, even after controlling for other factors. This has important implications for policy, as it suggests that changing the institutional environment of a region can have a significant impact on its economic performance.

Overall, Davis and Weinstein’s article demonstrates the power of natural experiments to shed light on important economic questions and inform policy debates. By examining the historical and geographical factors that have shaped economic activity around the world, they offer valuable insights into the mechanisms that drive economic growth and inequality.

Figure 3.1: Paul Krugman *1953¹

Before you read this article, let me explain that the theory which this article elaborates and tests goes back to the 2008 nobel-prize winner Paul Krugman (*1953) who founded the so-called *New Economic Geography* (NEG). Here is an excerpt of how the Royal Swedish Academy of Sciences summarizes Krugman’s contribution to the field (RSA2008Prize, 3):

¹Picture is taken from https://commons.wikimedia.org/wiki/File:Paul_Krugman-press_conference_Dec_07th,_2008-8.jpg

Economic geography deals not only with what goods are produced where, but also with the distribution of capital and labor over countries and regions. The approach Krugman used in his foreign trade theory – the assumption of economies of scale in production and a preference for diversity in consumption – was also found to be appropriate for analyzing geographical issues. This allowed Krugman to integrate two disparate fields in a cohesive model.

The embryo of the theory which would come to be called the “new economic geography” had already appeared in Krugman’s 1979 article. In the final pages, he asks what would happen if foreign trade became impossible, for instance due to excessively high transport costs or other obstacles. His line of reasoning is as follows. If two countries are exactly alike, then welfare will be the same in both countries. But if the countries are alike in all respects except that one of them has a slightly larger population than the other, then the real wages of labor will be somewhat higher in the country with more inhabitants. The reason is that firms in the more highly populated country can make better use of economies of scale, which implies lower prices to consumers and/or greater diversity in the supply of goods. This, in turn, enhances the welfare of consumers. As a result, labor, i.e., consumers, will tend to move to the country with more inhabitants, thereby increasing its population. Real wages and the supply of goods will then continue to increase even more in that country, thereby giving rise to further migration, and so on.

Twelve years would pass, however, before Krugman reconsidered these ideas. In an article published in 1991, he developed these concepts into a comprehensive theory of location of labor and firms. Here, he assumes that although trade is possible, it is obstructed due to transport costs. Otherwise, labor is free to move to the country or region which can offer the highest welfare, in terms of real wages and diversity of goods. Firms’ location decisions imply a trade-off between utilizing economies of scale and saving on transport costs.

Concentration or Decentralization?

The above considerations evolved into the so-called core-periphery model, which shows that the relation between economies of scale and transport costs can result in either concentration or decentralization

of communities. Under certain conditions, the forces which contribute to concentration will dominate. Regional imbalances arise and most of the population will be concentrated in a high-technology core, whereas a small minority will inhabit the periphery and live off agriculture. Such a mechanism could underlie the explosive urbanization witnessed today throughout the world, with rapidly growing megacities surrounded by increasingly depopulated rural areas. This is not necessarily the only possibility, however. Under different conditions, the forces which give rise to decentralization will dominate. This promotes somewhat more balanced development. Krugman's model can be used to account for the mechanisms at work in both directions. For example, his model indicates that declining transport costs easily generate concentration and urbanization – which seems particularly noteworthy since transport costs have exhibited a declining trend throughout the twentieth century.

Numerous research papers inspired by Krugman's New Economic Geography (NEG) focus on the origins and implications of the so-called first and second nature effects. These effects are used to explain the uneven distribution of economic activity both across countries and within regions of a country. Two primary explanations have been investigated: (1) *Fundamentals*, which refer to differences in the fundamental productivity of locations, and (2) *Agglomeration forces*, which are related to the proximity of economic agents that boost productivity and make a location more attractive.

These two mechanisms are obviously not exclusive and can both operate simultaneously. The key empirical question is to what extent observed patterns of economic activity are explained by these two mechanisms. Understanding whether fundamentals or agglomeration forces are responsible for the pattern of economic activity has significant implications for the persistence of spatial equilibria and policy making.

For instance, suppose only agglomeration forces are at play. In that case, the location of economic activity is relatively arbitrary, and a particular location is attractive mainly because other workers are choosing to locate there. This phenomenon is similar to selecting a nightclub: club A is crowded and everybody wants to be there only because it was the club had attracted the first person that night.

In contrast, if only fundamentals are in operation, the distribution of activity is determined by the distribution of these underlying factors. When agglomeration forces dominate fundamentals, the spatial distribution of activity becomes a matter

of political interest. For example, regional policies can aim to move the distribution of economic activity between different equilibria. Using a temporary subsidy, regions can try to attract a ‘critical mass’ of economic activity. Once established, this critical mass will make the location more attractive, even when the subsidy has ended.

This approach is similar to nightclub policies, such as offering free entry or other discounts to the first people who are searching for a club. These incentives are an attempt to attract a critical mass of party-goers, making the nightclub more attractive and increasing the likelihood that other party-goers will choose the same club later.

Exercise 3.1. The impact of nuclear bombs on agglomerations

Background: The bombing of Japan during the Second World War devastated 66 cities that were targeted, leading to the destruction of approximately half of their housing stock and the deaths of around 300,000 Japanese. Although Hiroshima and Nagasaki are more well-known due to the nuclear bombs that were dropped on them, the majority of cities in the sample suffered little to no destruction, including several large cities. Despite the scale of the bombing, it was clearly a temporary shock that did not change the fundamental attractiveness of locations. However, the nuclear radiation in Hiroshima and Nagasaki could be considered an exception.

Data: The data set used in the paper consists of information on 303 Japanese cities with a population exceeding 30,000 in 1925. Population figures are recorded every five years, with the exception of the 1945 census, which took place in 1947. One way to gauge the intensity of the shocks experienced by the cities is by looking at the number of dead or missing residents.

- a) Read [Davis and Weinstein \(2002\)](#)² and explain the implications of the following figures:

The results of Davis and Weinstein (2002) show a striking persistence of city size even after terrible wartime destruction. This has important implications for attempts to use regional policy to shift economic activity between spatial equilibria. The following quote sums it up well: > “An important practical question, then, is whether such spatial catastrophes are theoretical curiosities or a central tendency in the data. Our results provide an unambiguous answer: Even nuclear bombs have little effect on relative city sizes over the course of a couple of decades. The

²It is available here: <https://blogs.cuit.columbia.edu/dew35/files/2016/08/BBB.pdf>

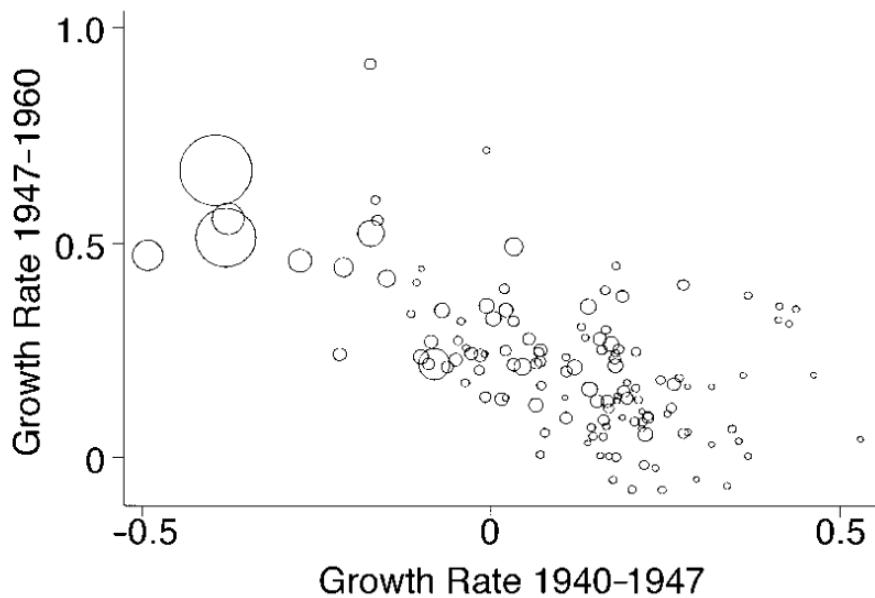

FIGURE 1. EFFECTS OF BOMBING ON CITIES WITH MORE THAN 30,000 INHABITANTS

Figure 3.2: Figure 1 of [Davis and Weinstein \(2002\)](#)

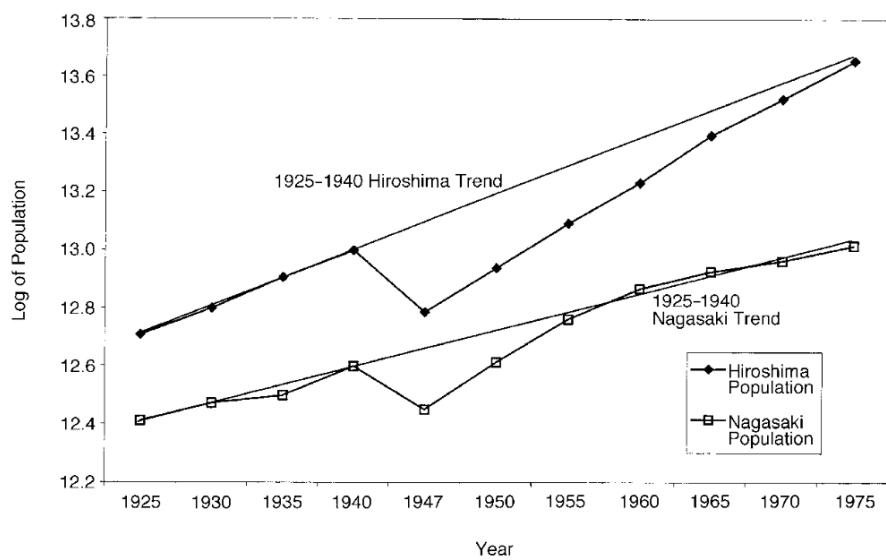

FIGURE 2. POPULATION GROWTH

Figure 3.3: Figure 2 of [Davis and Weinstein \(2002\)](#)

theoretical possibility of spatial catastrophes due to temporary shocks is not a central tendency borne out in the data.” [Davis and Weinstein \(2002, p. 1284\)](#)

The use of bombing as a temporary shock, however, can be seen as problematic: Although bombing causes casualties and destroys housing and social structures, legal property rights and operating licenses are not destroyed. Therefore, rebuilding cities may prove less burdensome than building new settlements from scratch. Moreover, even after a nuclear explosion, functioning infrastructure may still be in place, which could make rebuilding at the old site less costly.

- b) Read [Bleakley and Lin \(2012\)](#) and discuss how this is confronting the insights from ?. It is freely available here: <https://personal.lse.ac.uk/sturmd/brixen/pdf/Bleakley-Lin-QJE-2012.pdf>

Exercise 3.2. Natural experiments in research

- a) Think of other natural experiments that can be scientifically exploited.

Chapter 4

Hands on observational data

4.1 Difference in difference

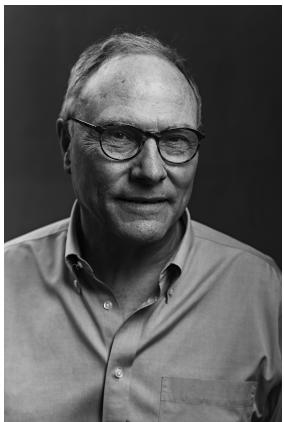

Figure 4.1: David Card (*1956)¹

David Card is one of the most influential labor economist of the 20th century and Nobel laureate of 2021. He is well-known for his research on the effects of the minimum wage on employment, which challenged the traditional view that increasing the minimum wage leads to a decrease in employment. In his article *Minimum Wages and Employment: A Case Study of the Fast-Food Industry in New Jersey and Pennsylvania* (Card & Krueger, 1994) he and Alan Krueger (1960-2019) used a *natural experiment* to examine the effect of an increase in the minimum wage on employment. In particular, they identified a treatment group (restaurants in

¹Photo stems from his public homepage <https://davidcard.berkeley.edu/>

New Jersey) and a control group (restaurants in eastern Pennsylvania) to measure the effect of increasing the minimum wage that was increased in New Jersey but not in Pennsylvania. This increase did not lead to a decrease in employment, which contradicted the widely held view that increasing the minimum wage would lead to job loss. The empirical method that they used is called *difference in difference* and we discuss it in the following section.

The difference in difference (DiD) method allows to estimate the causal effect of a treatment or intervention. In particular, it is popular to study the impact of policy changes and other interventions on a specific outcome of interest.

The basic idea behind the DiD method is to compare the change in an outcome variable between a treatment group and a control group over time. The treatment group is the group that is exposed to the intervention or treatment, while the control group is a group that is not exposed to the intervention. The difference in the change in the outcome variable between the two groups is then used to estimate the causal effect of the intervention.

To use the DiD method, researchers typically collect data on the outcome variable of interest for both the treatment and control groups before and after the intervention. This data is then used to calculate the difference in the change in the outcome variable between the two groups.

For example, if a study aims to examine the effect of a new policy on the employment rate, it should collect data on the employment rate for a group of individuals living in a region where the policy was implemented, and for a group living in a similar region where the policy was not implemented. The study can then compare the change in the employment rate for the two groups, before and after the implementation of the policy. The difference in the change in the employment rate between the two groups can be used to estimate of the causal effect of the policy on employment.

It is important to note that DiD assumes that there are no other factors that could be affecting the outcome variable of interest and that the treatment and control groups are similar in all ways except for the intervention. To control for these assumptions researchers can use statistical techniques such as matching to ensure that treatment and control groups are similar before the intervention.

DiD is useful when we only have observational data and in situations where it is not possible or ethical to randomly assign individuals to a treatment or control group, for example, in the case of policy changes.

The figures above stem from Brady Neal's lecture on *Difference-in-Differences* which can be found here: <https://youtu.be/2nDgrNP7XSE>. Please watch this video.

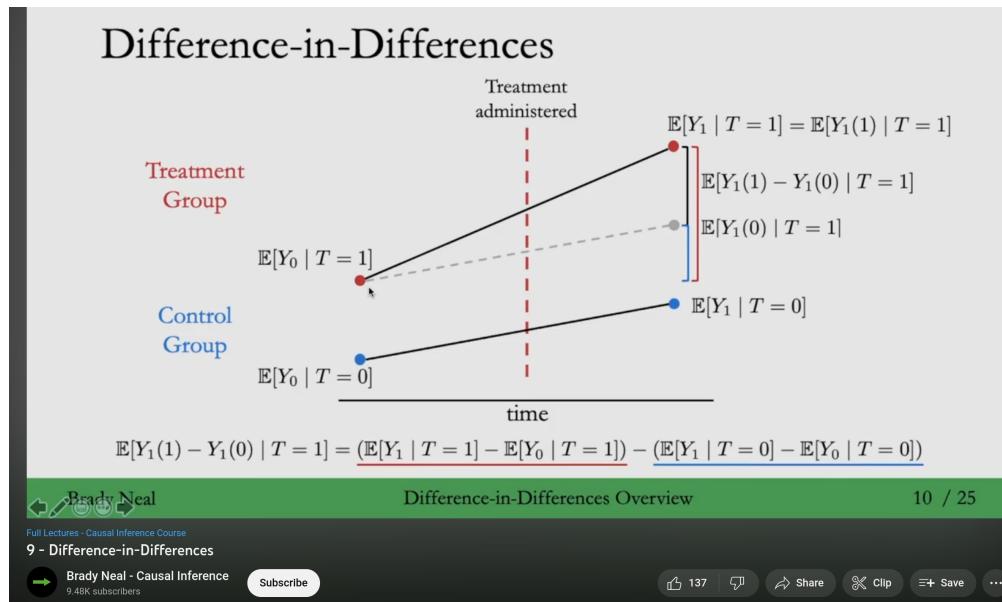

Figure 4.2: Differences-in-Differences

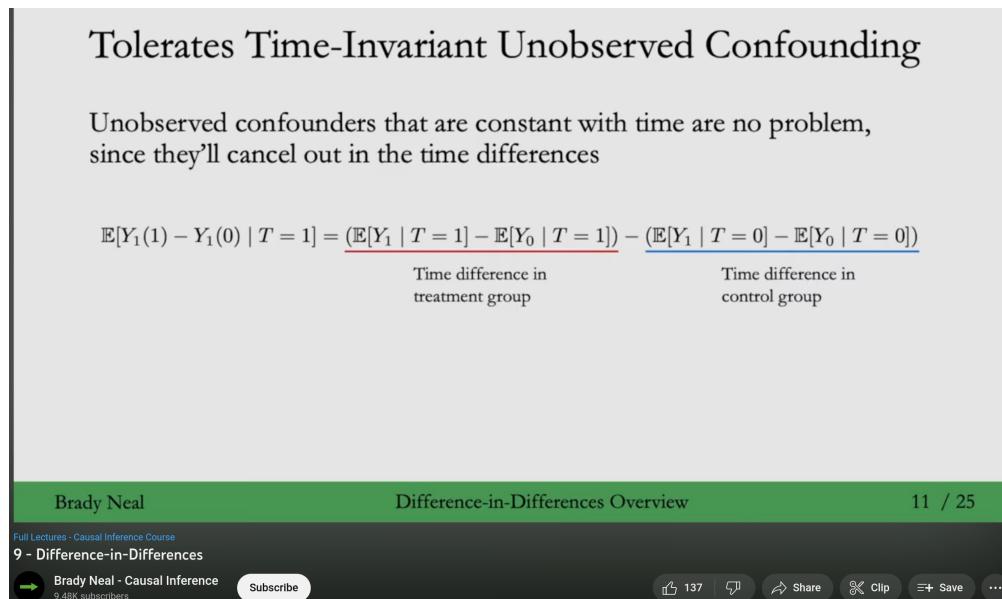

Figure 4.3: Tolerate time-invariant unobserved confounding

Exercise 4.1. Differences-in-Differences

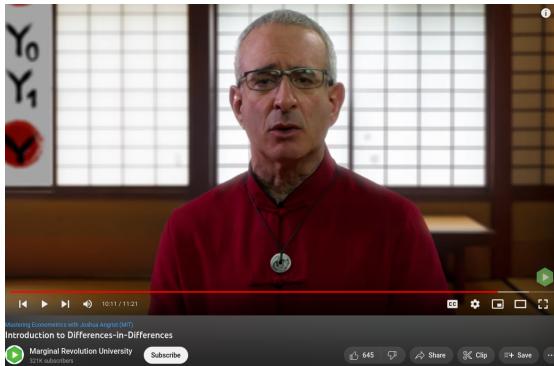

Figure 4.4: Josh Angrist (*1960): Nobel Prize winner of economics in 2021²

Watch the video *Introduction to Differences-in-Differences* found here: <https://youtu.be/eiff0VbYvNc> and answer the following questions. The video is part of a course called *Mastering Econometrics with Joshua Angrist (MIT)* produced by Marginal Revolution University. In it, Josh Angrist introduces differences within differences using one of the worst economic events in history: the Great Depression.

1. In the video, the treatment being examined is:
 - a) Bank failure.
 - b) “Easy” money.
 - c) “Tight” money.
 - d) Differences-in-Differences.
 - e) None of the above.

2. If the treatment were effective, which outcome would we expect to observe?
 - a) Fewer bank failures.
 - b) Increased bank failures.
 - c) Continued parallel trends.
 - d) No differences in any variables unrelated to bank failure.
 - e) None of the above.

3. Practically, how is DD (Differences-in-Differences) typically implemented?

²The picture stems from the video <https://youtu.be/eiff0VbYvNc>

- a. Non-parametric statistical techniques.
- b. Randomized trials.
- c. Regression analysis.
- d. Instrumental variables.
- e. None of the above.

Please find solution to the exercise [in the appendix](#).

Appendix

Solution to exercise 1.1: The Effect ch.1+2

Answers: 1. c), 2. c), 3. a)

Solution to exercise 1.2: Features of research

Answers:

1. a), 2. b), 3. c), 4. d), 5. c), 6. b), 7. c), 8. a), 9. d)

Solution to exercise 2.2: Causal inference ch. 1

Answers:

1. Some common misconceptions about causality that the author addresses in chapter 1 include confusion between correlation and causality, and the belief that observational studies cannot (hardly) establish causality without prior knowledge. He says that human beings “engaging in optimal behavior are the main reason correlations almost never reveal causal relationships, because rarely are human beings acting randomly” which is crucial for identifying causal effects.
2. The role of randomization in causal inference, as described in the book, is that it helps to control for confounding variables and allows for the estimation of causal effects.

Solution to exercise 2.3: Simpson's Paradox

- a) Assumption 1 is that in any given discipline male and female applicants do not differ in respect of their intelligence, skill, qualifications, promise, or other attribute deemed legitimately pertinent to their acceptance as students. It is precisely this assumption that makes the study of “sex bias” meaningful, for if we did not hold it any differences in acceptance of applicants by sex could be attributed to differences in their qualifications, promise as scholars, and so on. (...) Assumption 2 is that the sex ratios of applicants to the various fields of graduate study are not importantly associated with any other factors in admission. ([Bickel et al., 1975](#), page 398)
- b) Expectations were taken based on the overall acceptance rate of about 0.416 and multiplied by the total observed numbers of applicants admitted and rejected. For example: $(3738 + 4704) \cdot 0.41666 \approx 3460$ and $(3738 + 4704) \cdot (1 - 0.41666) \approx 4981$. Taking the difference of these two measures gives the number to be explained.
- c) The analogy is explained on page 400:

“Picture a fishnet with two different mesh sizes. A school of fish, all of identical size (assumption 1), swim toward the net and seek to pass. The female fish all try to get through the small mesh, while the male fish all try to get through the large mesh. On the other side of the net all the fish are male. Assumption 2 said that the sex of the fish had no relation to the size of the mesh they tried to get through. It is false.”

The UC Berkley case is just one of many examples to illustrate that uniformity of group assignment of individuals is a necessary condition to ensure that pooling of data does not lead to misleading conclusions when using statistics. The phenomenon of obtaining different results depending on whether one considers the data pooled or unpooled is often referred to as the *Simpson Paradox*.

Solution to exercise 2.4: Simpson's Paradox

Answers: 1. a), 2. c) and d)

Solution to exercise 2.5: Treatment effects

1. The individual treatment effect (ITE) is a measure of the effect of a treatment or intervention on an individual level. It represents the difference in the

outcome for an individual who receives the treatment versus the outcome for that same individual if they had not received the treatment.

2. The average treatment effect (ATE) is a measure of the difference in the expected outcomes between a treatment group and a control group. It represents the overall effect of a treatment on the population as a whole.
3. The ATE is calculated by taking the difference between the average outcome for the treatment group and the average outcome for the control group.
4. No, the ATE is a population-level measure and cannot be used to determine the effect of a treatment on an individual level. To determine the effect of a treatment on an individual level, you would need to use techniques such as propensity score matching or instrumental variables.
5. Some potential sources of bias when estimating the ATE include selection bias, measurement bias, and unobserved confounding variables. To mitigate these biases, researchers may use randomization or other advanced statistical techniques such as propensity score matching or instrumental variables to control for these potential sources of bias.

Solution to exercise 4.1: Differences-in-Differences

Answers: 1. b), 2. a), 3. c)
